Observational evidence that disk was formed from discrete clusters with unique multi-abundance signatures

M. Ness[1], V. Debattista[4]., David W. Hogg[1,2,3], H.-W. Rix[1], others?

ness@mpia.de

ABSTRACT

Text is gibberish; column captions are gibberish. Table of lowest 100 chi2 values are given. This is remarkable and confusing (vr,vt,vz of many pairs).

Subject headings: Galaxy: stellar content — methods: data analysis — methods: statistical — stars: evolution — stars: fundamental parameters — techniques: spectroscopic

1.

2. Introduction

We know that stars move from their birth radius, but not known if this is a perturbing process or else is the dominant effect in the disk as it is today. observationally we know that at a given age there is a wide metallicity range of stars (cite an AMR paper), that the youngest stars show tight relationship between [Fe/H] and Rgal (Cepheid paper) and that older stars show a weaker relationship (Ness 2016) than younger stars at a given [FE/H]-[alpha/FE] indicative at a given metallicity stars are distributed over a wider radial span as a consequence of moving from brith locations, (compared to cheeped plot). As radial migration process changes the orbit radii without a boost in the eccentricity, there is then not kinematic signatures that are left and no structural changes to the disk; hence the challenge

[4]UCLAN

in evaluating this process observationally. This has led to the field of galactic archeology - using detailed chemical abundances to find stars of common origin of birth. Conjecture by Freeman and Bland-Hawthron that stars in the disk are born in open clusters, which will have homogenous abundance and a unique abidance signature. Given this expectation, expect to be able to reconstruct the disk if you can locate stellar siblings, which is the mission of large high resolution spectroscopic surveys obtaining large numbers ($\sim$ 1 million stars) with measurements of 30 elements to probe litany of nucleosynthetic processes (Freeman 2012, da Silva 2015). Main challenges in this are precision until recently been not good enough, but now overcome (e.g. Hogg et al., 2016) and that systematic offsets as a function of (Teff, logy) in X/Fe measurements due to departures from non LTE (e.g. Yeisson , Karin) so whilst technical challenges in modelling overcome necessary to consider restricted parameter space in Teff, logg for comparison of multi-dimensional abundance space and also the numbers of stars; clusters are expected to be of size N x N solar masses, which means that in a samples of even hundreds of thousands of stars, only a few members of the same cluster - stellar siblings are to be expected to be found.

3. Data

4. Results

. . . If ΔR decreases with increasing number of abundances added, this implies that at a given metallicity of gas, the interstellar medium was not well mixed,

. . . - summarise the paper of YST and what they determined from APOGEE data and then point to section where show comparison of *The Cannon* 's results for the same elements as ASPCAP for YS's high alpha-sequence. Use spectral derivatives; also found comparable results using a 2 x resolution element wavelength window filter where every instance appears in the lines list; better for some and worse for others.

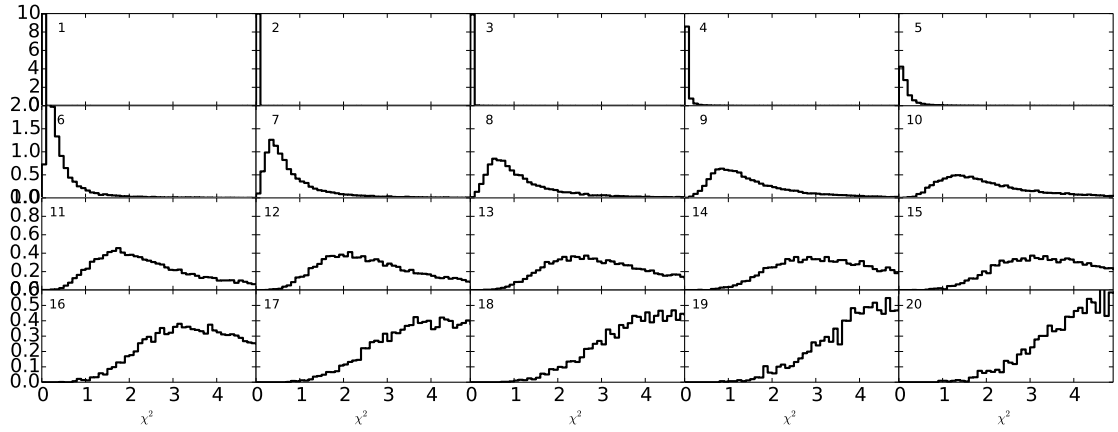

Fig. 1.— At left, neighbours of stars drawn at random with metallicities within the errors and at right the nearest neighbour for a 20 element chi2

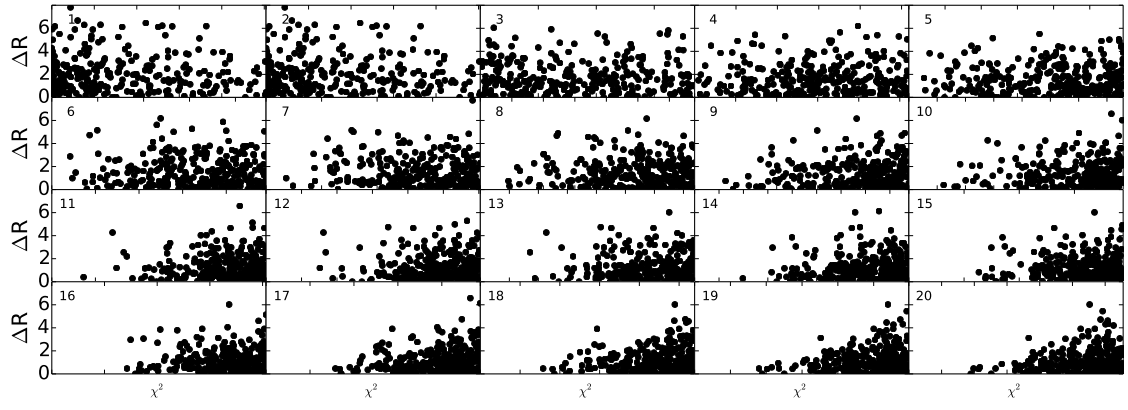

Fig. 2.— At left, neighbours of stars drawn at random with metallicities within the errors and at right the nearest neighbour for a 20 element chi2

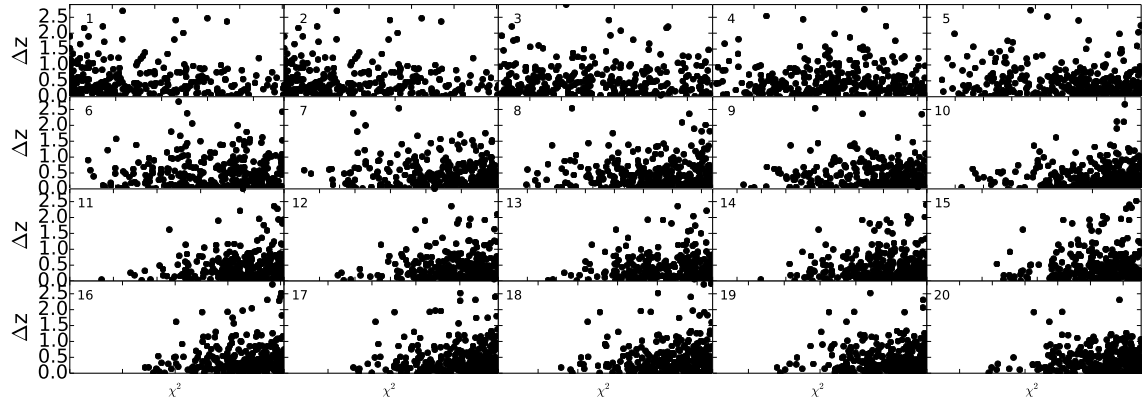

Fig. 3.— At left, neighbours of stars drawn at random with metallicities within the errors and at right the nearest neighbour for a 20 element chi2

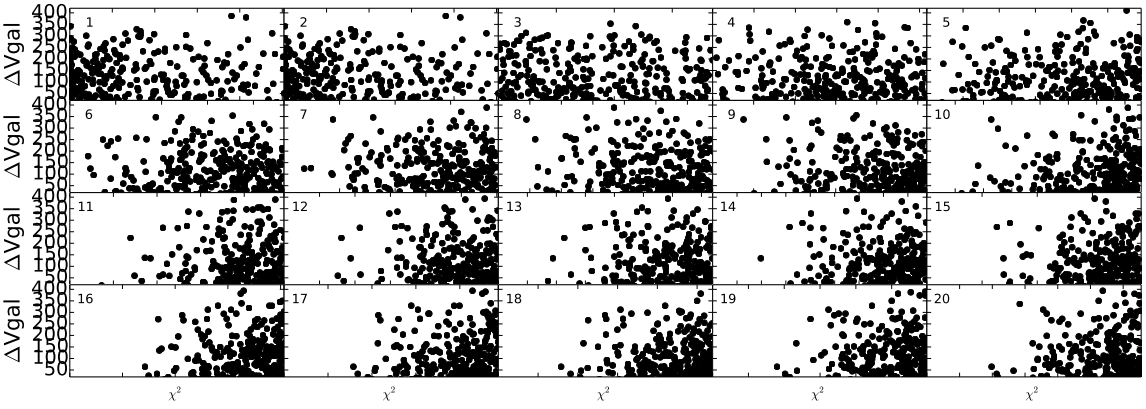

Fig. 4.— At left, neighbours of stars drawn at random with metallicities within the errors and at right the nearest neighbour for a 20 element chi2

. . . In Section X we demonstrate the improvement as a function of SNR compared to current approaches and compare filtered versus unfiltered approach. This demonstrates we achieve error bars which are 2-3 times smaller and this is critical for chemical tagging and also shows that can get higher precision labels with less observing time; can probe further out into the disk getting fainter targets or observe larger numbers of stars.

. . . In Section Y we demonstrate we are on the same scale as ASPCAP's high SNR data which shows an rms of x and as SNR decreases the rms increases, as a result of the lower fidelity of ASPCAP's results.

. . . different nucleosynthetic processes and so birth conditions

5. Notes

Over the past several years, however, this assumption of stars remaining near their birth radii has been firmly shaken by the realization that rapid stellar migrations of several kpc are possible (Sellwood & Binney 2002, hereafter SB02). Roskar 2012

6. Data

. . .

7. APOGEE value-added individual abundances catalogue

. . . criteria are closest in 20 abundance space + ages within 45%

. . . Note this shows that in the low alpha sequence - the youngest stars are along all metallicity and sit at a lower [Mg/Fe] than the older stars.

run -i plotgroupsnew

Acknowledgments

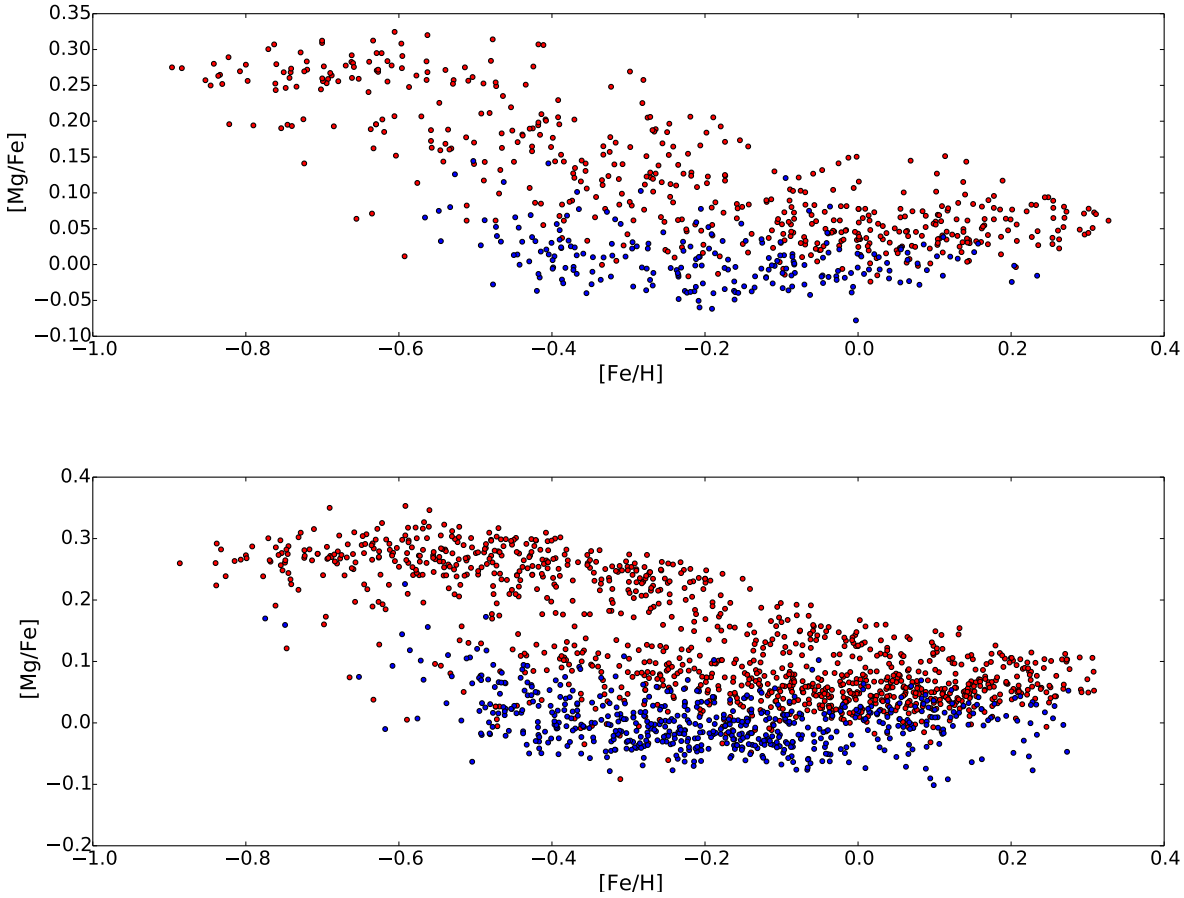

Fig. 5.— Mean values for the1000 pairs with chi2 < 5 shown with blue being ages < 2 Gyr and old being ages > 7 Gyr: at top just fe and at bottom is 20 elements

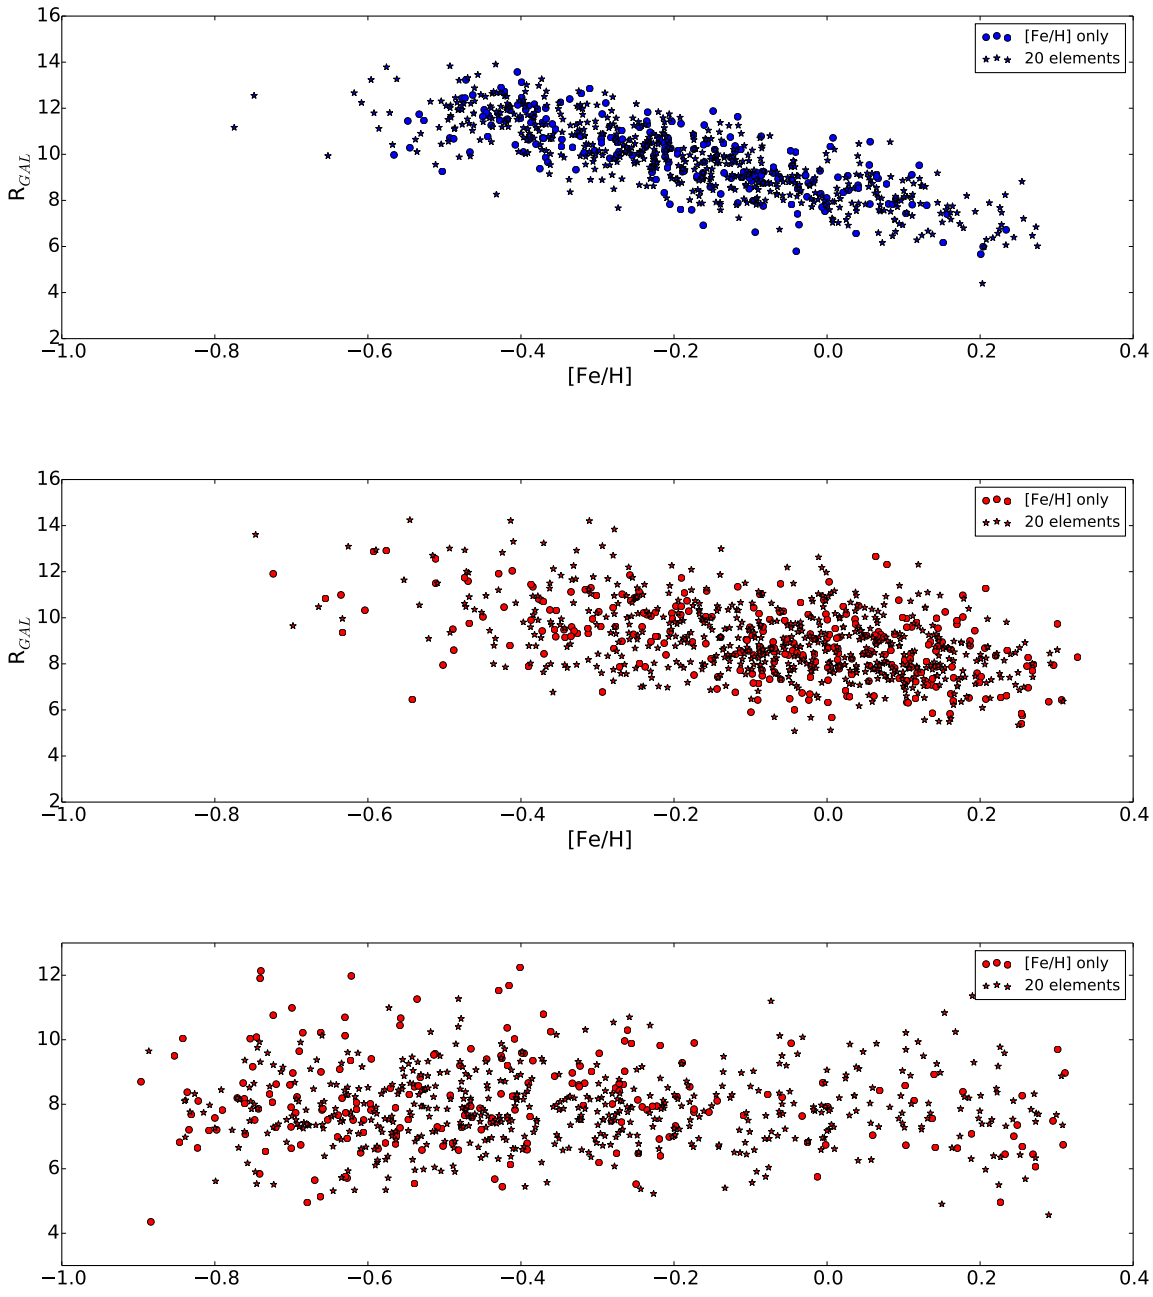

Fig. 6.— young pairs, old pairs in low alpha sequence, old pairs in high alpha sequence: looks the same if you select on just fe/h or in 20 element space

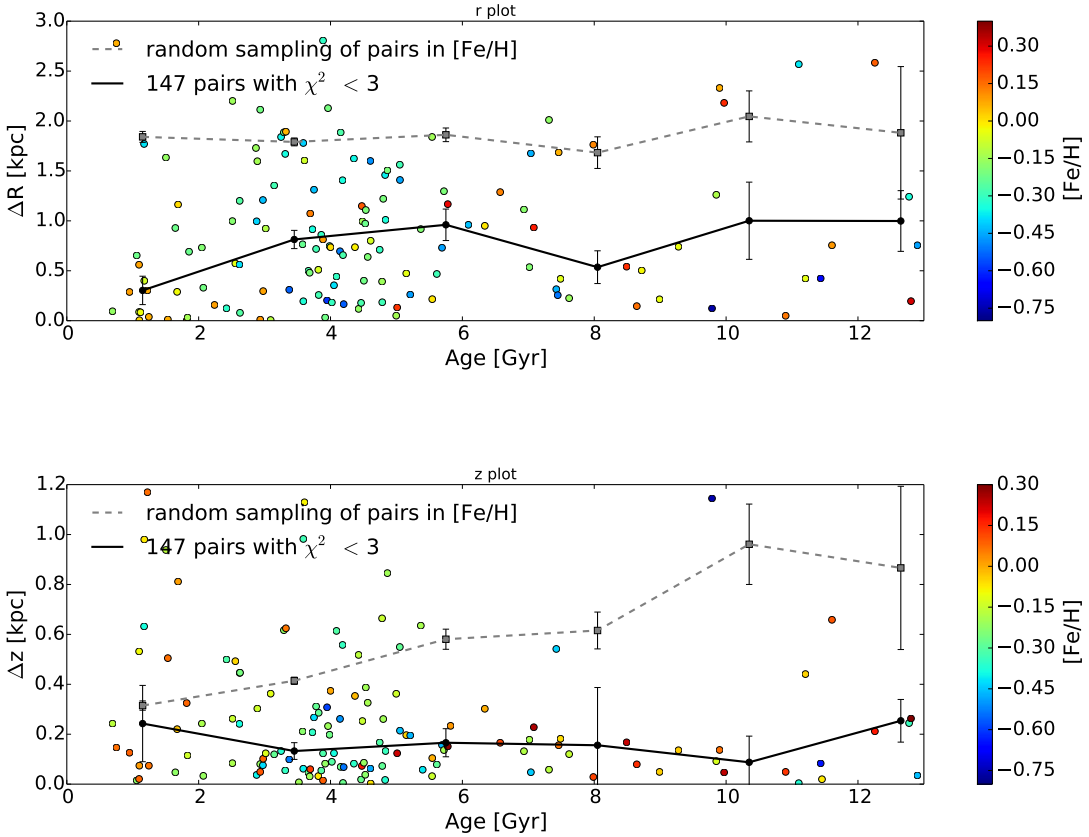

Fig. 7.— At left, neighbours of stars drawn at random with metallicities within the errors and at right the nearest neighbour for a 20 element chi2

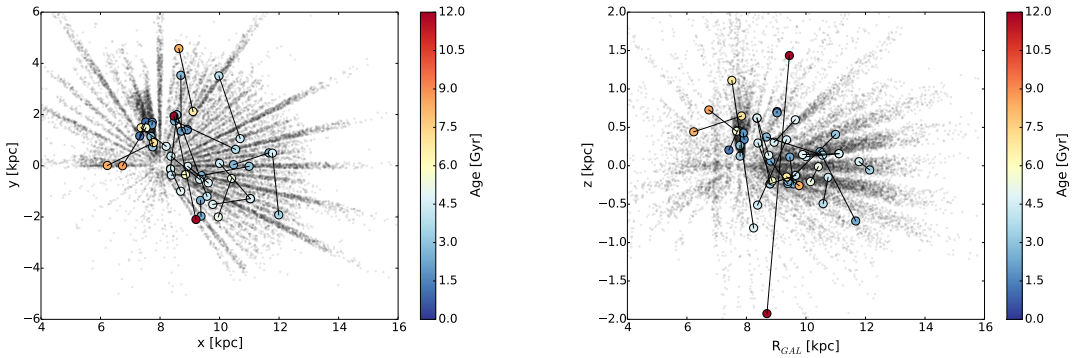

Fig. 8.— 25 nearest neighbours in 20 abundance space; metallicities span -0.75 to 0.3 dex.

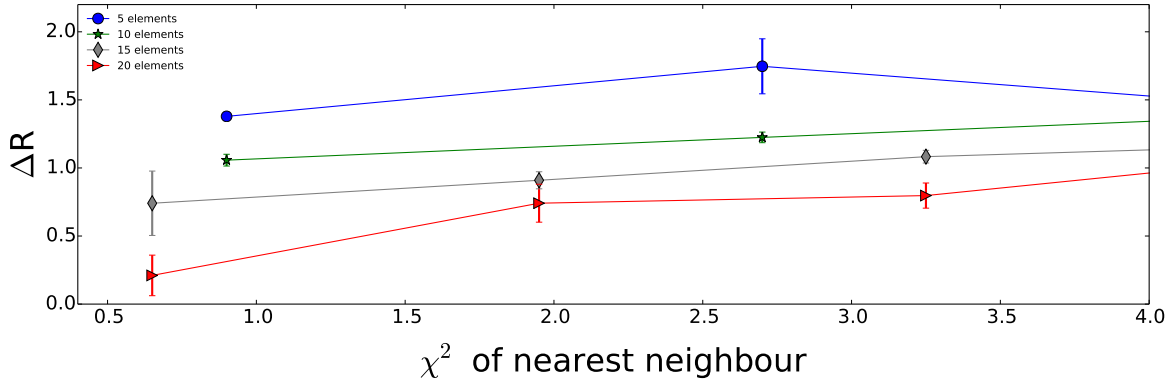

Fig. 9.— At left, neighbours of stars drawn at random with metallicities within the errors and at right the nearest neighbour for a 20 element chi2

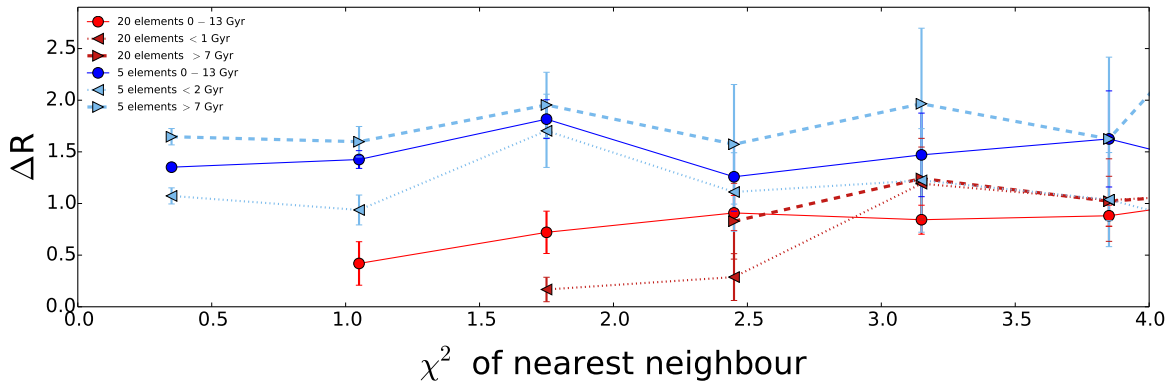

Fig. 10.— At left, neighbours of stars drawn at random with metallicities within the errors and at right the nearest neighbour for a 20 element chi2
